BACKGROUND

To better assess the water quality of a particular aquifer at a given point in time, an attempt was made during the project year to sample all project wells producing from a common aquifer in a narrow time frame. Also, to more conveniently and economically promulgate those data collected, these aquifer summaries will make up the project Triennial Summary Report.

Figure VII-1 shows the geographic locations of the Carnahan Bayou Aquifer and the associated project wells, whereas Table VII-1 lists the wells in the aquifer along with their total depths and the use made of produced waters and the date sampled.

These data show that in May of 1998, seven project wells were sampled which produce from the Carnahan Bayou Aquifer. Of these seven wells, five are classified as Public Supply, one is classified as Industrial, and one is Domestic. The wells are located in five parishes from the east central to the southwest part of the state.

PROJECT FIELD AND ANALYTICAL PARAMETERS

The field parameters that are checked at each sampling site and the list of water quality parameters that are analyzed in the laboratory are shown in Table VII-2. Those project inorganic (total metals) parameters analyzed in the laboratory are listed in Table VII-3. These tables also show the field and analytical results determined for each analyte.

In addition to the analytical parameters mentioned above, a list of project analytical parameters that include three other categories of compounds (Volatiles, Semi-volatiles, and Pesticides/PCB's) is included. Due to the large number of analytes in these three categories, tables were not prepared for each well. However, in order for the reader to be aware of the total list of analytes, Tables VII-4, VII-5, and VII-6 were included in this summary. The tables list the project analytes along with their Practical Quantitation Limits (PQLs) used during processing.

DISCUSSION OF WATER QUALITY DATA

FEDERAL PRIMARY DRINKING WATER STANDARDS: Laboratory data show that two project water wells in the Carnahan Bayou Aquifer that are both used as a public supply wells exceeded the Federal Maximum Contaminant Level (MCL) for Cadmium. A concentration of 6.1 ppb was reported for Vernon Parish well number V-566 and a concentration of 5.1 ppb was reported for Rapides Parish well number R-1210. It is believed that these concentrations are due to field contamination, however a final determination will be made pending further analyses.

Those project wells reporting Turbidity levels of >1 NTU, do not exceed the MCL of 1.0, as this primary standard applies to surface water systems only.

FEDERAL SECONDARY DRINKING WATER STANDARDS: Secondary standards are defined as non-enforceable taste, odor or appearance guidelines. Field and laboratory data contained in Tables VII-2 and VII-3 show that three of the wells sampled in the Carnahan Bayou Aquifer exceeded the Secondary Maximum Contaminant Levels (SMCL) for two analytes in this category.

IRON (SMCL=300 ppb):

CO-71 exceeded this secondary standard with a reported concentration of 3,664 ppb.

V-566 exceeded this secondary standard with a reported concentration of 3,732 ppb.

V-496 exceeded this secondary standard with a reported concentration of 1,647 ppb.

COLOR (SMCL=15 PCU):

V-496 exceeded this secondary standard with a reported concentration of 20 PCU.

FEDERAL LEAD ACTION LEVEL: Under the Federal Safe Drinking Water Act, EPA has established an Action Level of 15

ppb for Lead to ensure that this contaminant does not pose either a short-term or long-term health risk in drinking water. Laboratory data contained in Table VII-3 show that four of the wells sampled in the Carnahan Bayou Aquifer exceeded the Action Level for Lead. A final determination as to the occurrence of these exceedances will be made pending further analyses.

V-566 exceeded this action level with a reported concentration of 31.4 ppb.

BE-405 exceeded this action level with a reported concentration of 40.6 ppb.

V-496 exceeded this action level with a reported concentration of 17.7 ppb.

R-1210 exceeded this action level with a reported concentration of 17.4 ppb.

R-1001 exceeded this action level with a reported concentration of 20.0 ppb.

QUANTIFIABLE CADMIUM AND LEAD VALUES: Table VII-3 shows that seven quantifiable values for Cadmium and seven quantifiable values for Lead were found in the laboratory analyses. These values are shaded in Table VII-3. It is believed that these values are due to the grade of acid that was used to preserve the samples. Resampling has been done on wells in other aquifers using a higher grade of acid so that a determination may be made on this matter.

SELECTED WATER QUALITY MAPS

For the reader's convenience, maps showing the contoured values for pH, TDS, Chloride, and Iron are included in this summary report in Figures VII-2 through VII-5.

SUMMARY AND RECOMMENDATIONS

In summary, the analytical data show the ground water from this aquifer to be of good quality, with the exception of the unconfirmed exceedances discussed previously. A final determination as to the occurrence of these exceedances will be made pending further analyses.

It is recommended that the several project wells assigned to the Carnahan Bayou Aquifer be resampled as planned, in approximately three years. In addition, several wells should be added to those currently sampled to increase the well density for this aquifer.
